Question What is the structure of DNA and who discovered its double helix form? DNA has a double helix structure composed of two strands of nucleotides, and it was discovered by James Watson and Francis Crick in 1953. What are the four nucleotide bases in DNA, and which bases pair together? The four nucleotide bases are adenine (A), thymine (T), cytosine (C), and guanine (G). Adenine pairs with thymine, and cytosine pairs with guanine. Explain the process of DNA replication. DNA replication is the process where the double helix unwinds, and each strand serves as a template for the formation of a new complementary strand, resulting in two identical DNA molecules. What is the role of RNA in protein synthesis? RNA acts as a messenger that carries genetic information from DNA in the nucleus to the ribosomes, where proteins are synthesized through translation. Define mutations and give an example of a possible effect on an organism. Mutations are changes in the DNA sequence that can lead to variations in traits. For example, a mutation might cause a genetic disorder or, alternatively, provide beneficial traits that improve survival. What is genetic inheritance and how does it relate to dominant and recessive genes? Genetic inheritance is the passing of traits from parents to offspring. Dominant genes mask the effect of recessive genes when present, determining the organism's physical traits. How does DNA sequencing help in understanding genetics? DNA sequencing determines the exact order of nucleotides in a DNA molecule, helping scientists understand genetic variations, identify mutations, and study evolutionary relationships. What is the significance of complementary base pairing in DNA replication? Complementary base pairing ensures accurate copying of the genetic code during DNA replication, as each base pairs specifically with its partner (A with T, C with G), maintaining genetic integrity.
